Received September 18, 2014; Revised December 20, 2014

Sunflower oil produced by Pearl Ltd Veliko Tarnovo, with addition of Bulgarian herbs (oregano, thyme and pine cones) has been studied. The starting sunflower oil is a linoleic type containing predominantly linoleic acid (C₁₈:₂ = 521 g.kg⁻¹), followed by oleic (C₁₈:₁ = 344 g.kg⁻¹) and palmitic (C₁₆:₀ = 115 g.kg⁻¹) acid. Upon the examination of fatty acid composition of sunflower oil with various herbs supplements an increase of the oleic acid from 344 g.kg⁻¹ in the control to 422 ± 441 g.kg⁻¹ in the extracts has been found. Oleic / linoleic acid ratio varies between 0.95 and 1.10 in the extracts, whereas in pure sunflower oil it is about 0.66. This ratio indicates a better balanced composition in terms of the nutritional value of the tested samples. Adding herbs to the oil reduces the content of tocopherols (from 721 mg g⁻¹ to 388-459 mg.g⁻¹), which has an impact on its oxidative stability. Adding pine cones to sunflower oil reduces its oxidative stability about 3 times (from 10.8 h to 3.5 h), while the addition of oregano and thyme to the oil leads to minor change in oxidative stability (from 10.8 h to 7.6h). Therefore, sunflower oil with addition of herbs is inappropriate for heat treatment, but can be used for sauces, dressings, mayonnaise, and creams with exception of the sample with addition of the pine cones. Color parameters of oils in SIELab colorimetric system have been studied. It was found that the addition of oregano and thyme does not influence significantly the brightness of the samples and leads to an increase in their green components, which is associated with an increase in chlorophyll content from 0.003 ppm for pure sunflower oil to 0.094 ppm - 0.117 ppm for samples with oregano and thyme. The addition of both recent herbs result in double increase the content of β-carotene, respectively from 2.76 ppm for the control to 4.92÷ 5.77 ppm for the oil samples with oregano and thyme.

INTRODUCTION

Sunflower oil is lipid product typical for Bulgaria with large application in cookery and food industry. Its consumer qualities depend mainly on its fatty acid composition, the content of tocopherols (vitamin E), and of the possibilities to be stable during long term storage and thermal treatment. The main component of triacylglycerol fraction in conventional sunflower varieties is linoleic acid - 500 – 800 g.kg⁻¹, which belongs to the essential fatty acids that are vital for the human body. Due to its unsaturated nature, it is easily amenable to oxidation processes under the influence of light and oxygen from the air, a result of which the sunflower oil relatively quickly loses its consumer properties. Numerous attempts to increase its oxidative stability by the addition hereto of various natural and synthetic antioxidants have been made.

Bulgaria is reach in great variety of herbs that contain a high percentage of biologically active substances. They are rich in various compounds: alkaloids, glycosides, saponins, polysaccharides, tannins, flavonoids, lignans, coumarins, essential oils, vitamins, trace elements etc. In this regard, it is interesting to carried out investigations on the composition and stability of sunflower oil when adding thereto of various kinds of herbs Bulgarian.

The main objective of presented study is the examination of fatty acid and tocopherol...
composition, oxidative stability and color parameters of oil extracts from Bulgarian herbs (oregano, thyme and pine cones) with a view to their application in salads, sauces and other food products.

**EXPERIMENTAL**

Sunflower oil, production of Pearl Ltd Veliko Tarnovo, is used for conducting surveys. The oil extracts were prepared in a ratio of 1:5 (herb/sunflower oil), and were kept under refrigerated conditions (0°C-4°C) for 6 months.

**Analysis of fatty acids.** The fatty acid composition of oils was determined by gas chromatography (GC) after transmethylation of the respective sample with 20 g kg⁻¹ H₂SO₄ in absolute CH₃OH at 50°C [1]. FAME were purified by TLC on 20x20 cm plates covered with 0.2 mm silica gel 60 G (Merck, Darmstadt, Germany) layer with mobile phase n-hexane:dioxan 96:4 (by volume), flow rate 1.0 ml/min, excitation 295 nm, and emission 330 nm. 20 μL 10 g kg⁻¹ solution of oil in hexane were injected. Tocopherols were identified by comparing the retention times with those of authentic individual tocopherols. The identified tocopherols are identified by their peak areas in the sample versus authentic individual tocopherols. The tocopherol peak areas in the sample versus authentic individual tocopherols were calculated on the basis of those of authentic individual tocopherols. The tocopherol peak areas were measured by HPLC using special software.

**Fatty acid composition of the studied oil extracts** is presented in Table 2. Fatty acid composition is one of the main indicators characterizing the nutritional value of the oils and their oxidative stability during storage and heat treatment. The used sunflower oil has predominately linoleic acid content (521 g kg⁻¹), followed by oleic (344 g kg⁻¹) and palmitic (115 g kg⁻¹), which associates it with the oils of linoleic acid in the range of, where the linoleic acid quantity varies in range 480-740 g kg⁻¹, and the oleic one – 140-390 g kg⁻¹. It does not differ significantly from previously studied linoleic type oils in Bulgaria, and its composition is closest to that already obtained from Bulgarian sunflower variety "Musala". The ratio oleic/linoleic acid for oil extracts varies between 0.95 and 1.10, while for control sample it is around 0.66. Last ratio evidences better balance of fatty acid content, which is determining for nutritive value of the tested samples. Comparatively high content of linoleic acid indicates good nutritive value of oil extracts, because this acid belongs to human body essential fatty acids. The content of oleic acid in oil extracts is higher with 80 – 100 g kg⁻¹ compared to the control.

Data about total tocopherol content and composition of oils are presented in Table 2. Control sample has the highest content of tocopherols (721 mg kg⁻¹), while in the oil extracts its content decreases (388 - 459 mg kg⁻¹). In the oil extracts mainly saturated derivatives α- and β-tocopherols are identified. Basic representative of tocopherols in these oil extracts is α-tocopherol (945 – 961 g kg⁻¹).

The results from the investigation of oxidative stability of oil extracts are presented on Figure 1.

Fig 1. Oxidative stability of oil extracts

Oil extracts of oregano and thyme have lower oxidative stability (with about 3 hours) compared to the control, while the stability of the extract of pine cones is about three times lower than this of the control sample. Therefore, the last extract is not suitable for flavoring sunflower oil, as it leads to rapid oxidation and the oil is unsuitable for use in salads, sauces and more culinary products. Sunflower oil with added oregano and thyme is unsuitable for heat treatment, but due to its well-balanced nutritional value is useful for consumption in salads and sauces. The oil with oregano and thyme oxidative stability is comparable with that of cold-pressed walnut oil, which is used as a delicacy oil dressings for salads, sauces and meals.

Fig 2. Basic color coordinates of oil extracts from Bulgarian herbs in SIELab colorimetric system

The data for color parameters in SIELab colorimetric system allows calculating the color difference (ΔE) with respect the basic sample (sunflower oil). The biggest color difference is obtained for the extract of pine cones (ΔE = 21.6), while the color differences for those of oregano and thyme with control samples are compatible, being
respectively 10.9 and 13.0. The brightness of the extract of pine cone (65.14) has highest difference with the one of control sample (85.30). For the rest of the samples the change is not significant. Basic color coordinates are presented on Figure 2.

Oil extracts with oregano and thyme have high content of β-carotene and chlorophyll. The extract of pine cone also demonstrates essential rise of these parameters, but it worsens the gustatory qualities of the sunflower oil and nevertheless it enriches the oil, it makes the oil inapplicable for using in salads, sauces and other food products. The result is shown on Figure 3.

*Fig. 3.* β-carotene and chlorophyll content in samples of sunflower oil with addition of herbs.

**CONCLUSION**

Comparatively high content of linoleic acid and tocopherols in studied oil extracts shows their balanced nutritional value. Bulgarian herbs (oregano, thyme and pine corns) added to sunflower oil have prooxidative effect and the obtained oil extracts are inconvenient for thermal treatment. Due to the higher ratio oleic/linoleic acid the oil extracts of oregano and thyme can be used as delicacy dressings for salads, sauces and meals. Oil extracts of oregano and thyme have unchanged brightness and increased contents of chlorophyll and β-carotene, while the extract of pine corn has decreased brightness and increased color difference to the control.

(Резюме)
Слънчогледово олио с добавка на Български билки (риган, мащерка и шишарка),произведено от Pearl Ltd Veliko Tarnovo е изследвано. Посоченото олио е линоленов тип с доминиращо съдържание линоленова киселина (C₁₈:₂ = 521 g.kg⁻¹), следвана от олеинова (C₁₈:₁ = 344 g.kg⁻¹) и палмитинова (C₁₈:₂ = 521 g.kg⁻¹), киселини. Отношението на олеинова към линоленова варира между 0.95 и 1.10 в екстрактите, докато в чистото слънчогледово олио е около 0.66. Това отношение показва добре балансиран състав от хранителна стойност в тестваните образци. Добавянето на билки в слънчогледовото олио намалява съдържанието на токофероли (от 721 mg.kg⁻¹ до 388-459 mg.kg⁻¹), което влияе върху оксидантната стабилност. Добавянето на шишарка в слънчогледовото олио намалява оксидантната стабилност 3 пъти (от 10.8 часа до 3.5 часа), докато добавянето на риган и мащерка водят до минимална промяна в оксидантната стабилност (от 10.8 до 7.6 часа). Следователно слънчогледовото олио с добавка на билки е неподходящо за термична обработка, но може да бъде използвано за сосове, дресинги, майонези и други, с изключение на образците с добавянето на шишарка.

Изучени са цветовите характеристики на олиото в SIELab колориметрична система. Добавянето на риган и мащерка не влияят на светлотата на образците и водят до нарастване на тяхната зелена компонента, което се свързва с нарастването на хлорофилното съдържание от 0.003 ppm за чисто слънчогледово олио до 0.094 ppm-0.117 ppm за образци с риган и мащерка. Добавката на посочените две билки води до двойно нарастване на β- carotene от 2.76 ppm до 4.92-5.77 ppm за образците с риган и мащерка.
